

# Syntax-Semantic Interface and Tree Adjoining Grammar

Djamé Seddah

NCLT, DUBLIN

01/18/06

# Objective: to build a predicate argument structure from a TAG analysis

From a Tree Adjunct Grammar (TAG) analysis, we want :

- ▶ to build a deep syntactic structure with all argumental relations represented
- ▶ to have all the analysis in the same structure

We claim it is possible if we work directly in a structure which combines **derived tree** and **derivation tree** : **A shared forest**

# What is an interface between syntax and semantic ?

A way to construct a semantic meaning of a given sentence.  
So, what do you mean by semantic meaning ?

- ▶ a logical formula ?
- ▶ a dependency graph ?
- ▶ a predicate argument structure ?

Even, if they provide different level of informations, they rely on the same principle :The Freege theorem.

The meaning of an expression is a function of the meanings of its parts

# Implication of The Freege Theorem 1/2

- ▶ If we associate minimal sense to each part of a sentence
  - ▶ If we provide an interpretation function  $f$
- ⇒ *We can obtain a meaning*

let's do that for “(1) Tarzan loves Jane” and let  $f$  assigns the first argument of 'LOVE to the longest noun :

Tarzan	:	'TARZAN
loves	:	[1] 'LOVE [2]
Jane	:	'JANE

Semantic meaning of (1) : 'TARZAN 'LOVE 'JANE

*But “(2) Jane loves Tarzan” has the same meaning ! We must rely on a better interpretation function and for that we may use the order induced by syntax to assign argument positions to words.*

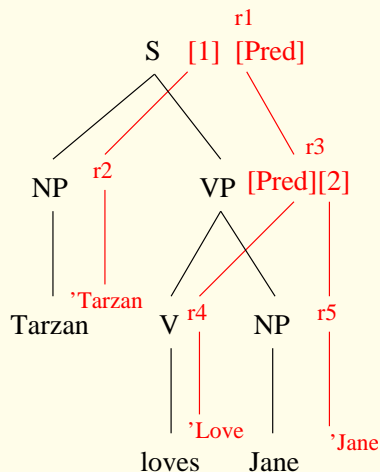

## Implication of The Freege Theorem 2/2

- ▶ Providing this mini model :

r1	S	→	NP VP		([1]=f(NP)) ([PRED]=f(VP))
r2	NP	→	Tarzan		'TARZAN
r3	VP	→	V NP		' ([PRED]=f(V)) ([2]=f(NP))
r4	V	→	love		'LOVE
r5	NP	→	Jane		'JANE

- ⇒ *We have to apply the rules and therefore to follow the derivations to get the proper result*

# Applying this model

- After the applications of the derivation rules, we obtain :
  - **'TARZAN 'LOVE 'JANE**
- ⇒ Once again, we have the correct interpretation
- ⇒ But what if we want to analyze "Jane is loved by Tarzan" ?

# Applying this model

Syntactically speaking we have 2 options :

- ▶ adding the following rules :

r3 VP  $\rightarrow$  V' PP ([PRED]=f(V)) ([1]=f(PP))

r6 V'  $\rightarrow$  be loved 'LOVE

r7 PP  $\rightarrow$  Prep NP [PRED]=f(NP)

r8 .. ..

$\Rightarrow$  *We have to modify deeply the corresponding semantic rules (r1 for the inversion of the arguments, etc..)*

- ▶ trying to use the fact that we are still trying to express relation between words even if this is hidden by the mechanism behind the rules

$\Rightarrow$  *So we should try to lexicalize this grammar a little bit...*

if we replace the main VP rules by :

r3 VP  $\rightarrow$  love NP 'Love ( $[1]=f(NP)$ )

r3' VP  $\rightarrow$  be loved GP 'Love ( $[2]=f(PP)$ )

The model is a lot more readable and simplified but the problem of the inversion argument in rule r1 is still here

## Lexicalization and semantic 2

Let's consider these 2 trees :

Active Parse Tree

Passive Parse Tree

- ▶ Assume that the red part is a single unit, called  $\alpha_{active}$  (resp.  $\alpha_{passive}$ ) and represents by itself a set of derivation rules

## Lexicalization and semantic 3

We could then express the derivation trees differently

Observations :

- ▶ They are very similar
- *w.r.t to the order of the arcs*
- ⇒ *one solution : numbered the nodes according to argument positions*
- ⇒ *Implicit : one argument position is linked to a derivation operation on a leaf node of  $\alpha_X$*
- ⇒ *Hypothesis : would it be simpler to deal with trees instead of rules -> it would simplify the semantic model*

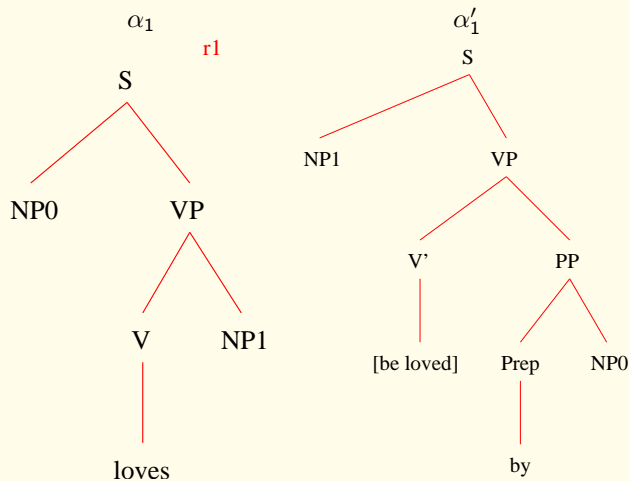

# Dealing with trees

let's call  $\alpha_2$  and  $\alpha_5$  the tree corresponding to  $r_2$  ( $NP \rightarrow \text{Tarzan}$ ) and  $r_5$  ( $NP \rightarrow \text{Jane}$ ) :

## Dealing with trees 2

let's call  $\alpha_1$  the tree corresponding to  $\alpha_{active}$  (resp.  $\alpha'_1$  and  $\alpha_{passive}$ ) :

► Notice the number on the leaf nodes

# Dealing with trees 3

analysis for “Jane is loved by Tarzan”:

## Dealing with trees 4

Result : Derived Tree (Parse Tree) and Derivation Tree (History of what have been derived).

## Pause : Where is the semantic model ?

- ▶ the derivation tree here is the semantic model
  - ▶ take the head as a predicate
  - ▶ take its leaves as its arguments
- ⇒ *a predicate-argument structure, or a first order term*
- ⇒ *We do not need anymore the manually crafted semantic rules*

# How is it possible ?

- ▶ Lexicalization :
- ⇒ *Each unit of the grammar is anchored by a lexical unit*
- ▶ Minimal Semantic Principle
- ⇒ *Each tree must correspond to a minimal semantic unit (msu)*
- ▶ predicate-argument cooccurrence principle
- ⇒ *Each argumental leaves nodes of a tree has to be fully realized*

this the so famous Well formedness principles

# Where is the adjunction ?

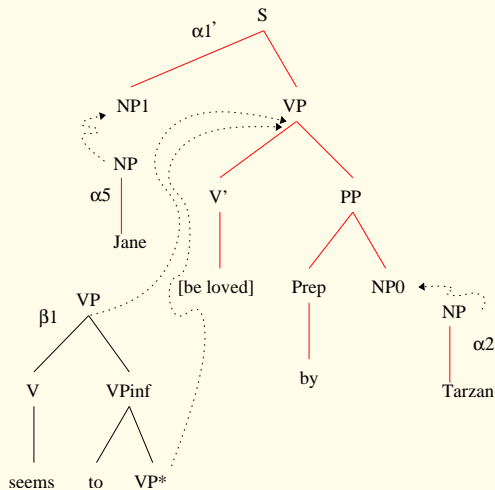

So far, we described only Lexicalized Substitution Tree Grammars. In order to fully lexicalized CFG, we need an optional operation of tree insertion : The adjunction.

- ▶ only a certain type of tree can be adjoined :  
The auxiliary tree (always prefixed by  $\beta$ )
- ▶ they must have a leaf node, the foot node with the same label than the root of the tree, the path from the root to the foot is called the spine
- ▶ let's  $\beta_1$  the auxiliary tree for the raising verb “to seem” :

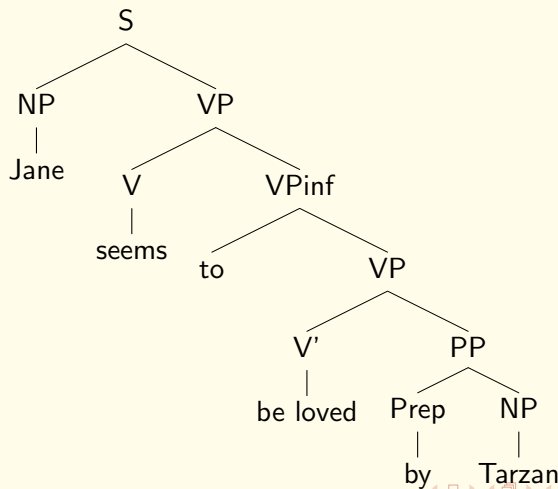

# Example of adjunction 1/3

Analysis for “Jane seems to be loved by Tarzan” :

## Example of adjunction 2 /3

Result : Derived Tree

]

## Example of adjunction 3/3

Results (suite) : Derivation tree for “Tarzan seems to love Jane” :

- ▶ the link between  $\beta_2(\text{seem})$  and  $\alpha_1'(\text{love})$  do not reflect a dependency relation but a modifier one (it's of course disputable)
- ▶ depending of the type of anchors (predicative or modifier), the adjunction link can be in the other direction.... Here are come the problems we will discuss the next time.

- ▶ Grammar contains elementary trees (initial and auxiliary trees)
- ▶ each tree is anchored by a lexical unit
- ▶ Two operations : substitution and adjonction
- ▶ As opposed to CFG, derivation tree and derived tree are not isomorphic anymore
- ▶ As opposed to LFG and HPSG, parsable in polynomial time

# Operations on trees

- **The substitution** is a context free derivation of an initial tree to a leaf node of any elementary tree

- **The adjunction** is a contextual insertion operation of an auxiliary tree within an elementary tree

# Derivation and derived trees

- ▶ Derivation tree : describes the derived tree construction (*i.e* the strict record of the operations used to parse a sentence)
- ▶ Derived tree : syntactic structure of a sentence
- ▶ Ex: Given the trees  $\gamma$  and  $\beta$ , with  $\beta$  adjoined on the node 1 of  $\gamma$

Arbre de dérivation

Arbre dérivé

Differences with other formalism :

- ▶ Features are atomic values only and then non reentrant
- ⇒ *Features are used only to control the subcategorization frame and to restrict the number of possible derivations according to a feature value*
- ⇒ *because of the adjunction, features are splitted into 2 fields by node : the top field and the bottom field*
- ⇒ *No Slash feature in TAG*

Adjunction : Update of the features

Substitution : Update of the features

Illustration on a feature  $V_{inf}=+$  :

If we want to be sure that  $\beta_2$  adjoin on tree with an infinitive, we have to add some informations to this tree :

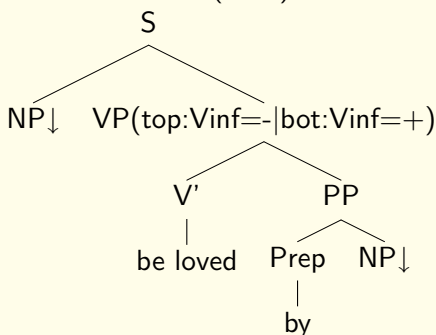

Tree  $\beta_2$

# Unification and Features Structure

Illustration on a feature  $V_{inf}=+$  : (suite)

Tree  $\alpha'_1$

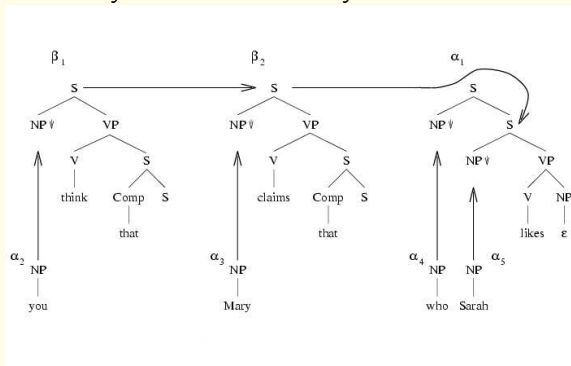

*By having two different top and bottom values on the node VP, we force the adjunction of an auxiliary tree of root VP and whose foot node has the value  $top:V_{inf}=+$ , therefore no more unification clash.*

# Long Distance Dependencies

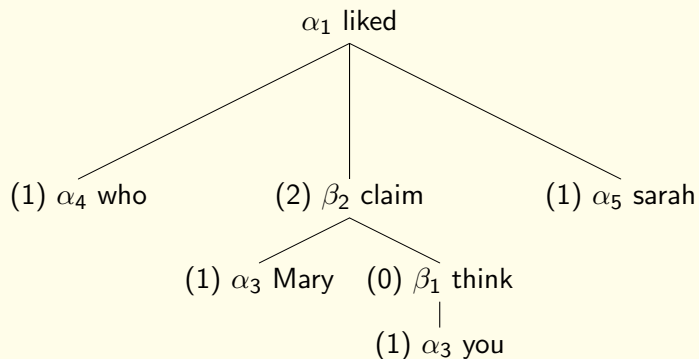

## Derivation Process

*Who do you think that Mary claim that Sarah liked ?*

# Long Distance Dependencies 2

## Derivation Tree

# Long Distance Dependencies 3

## Derived Tree

## Outline

- ▶ Is the Derivation Tree a good structure for Semantic ?
- ▶ Is it Possible to Use both Derived Tree and Derivation Tree for that ?
- ▶ What are Shared Forests, Derivation Forests or Dependency Forests ?
- ▶ What more can we do than Regular LTAG ? (control, ellipsis..)
- ▶ What are Multi-Component TAG, Synchronous TAG and Metagrammars ?
